To the Editor, Coronary revascularization procedures are used to treat coronary artery diseases, including acute coronary syndrome (ACS) and coronary artery chronic total occlusion (CTO) ([@ref1]). However, CTO is one of the major causes of mortality and morbidity ([@ref2]). After successful CTO recanalization, the optimal coronary stenting technique is still an open issue ([@ref3], [@ref4]). When compared with bare metal stents (BMSs), drug-eluting stents (DESs) have a better performance in the reduction of restenosis ([@ref5]). Currently, DESs are used in approximately 10% of all coronary revascularization procedures. However, their use in CTOs is still controversial. The main concerns about DES use in CTOs include: (1) concerns about their increased risk of late stent thrombosis (ST) ([@ref6]); (2) concerns about their possible detrimental impact on the final outcome in terms of recurrent CTO ([@ref7]); (3) their use in high-risk patients who are at higher risk of major adverse cardiovascular events (MACE) ([@ref8]). In our center, CTO recanalization procedures are performed according to the local standard protocol. Generally, a combination of aggressive cutting at the proximal edge and cutting balloon is used for successful and reliable recanalization. In our center, we mainly use sirolimus-eluting stents (SESs). In this study, we analyzed our experience with the use of SESs for CTO recanalization. We retrospectively evaluated 70 CTOs in 70 patients who were referred to our center for CTO recanalization between 2013 and 2016. All patients were candidate for coronary artery bypass graft surgery. They all had successfully CTO recanalization, with a successful final outcome according to the TIMI flow grade. After a median follow-up period of 12 months, one patient who had no
